AB A cathode structure for alkaline manganese dioxide-zinc primary or rechargeable cells with improved capacity that comprise manganese dioxide active material, a conductive powder and an additive material uniformly mixed and pressed to form a porous body, wherein the additive is a barium compound which is at least 3% mass of the solid components. The preferred additive is barium oxide , barium hydroxide or barium sulfate. The invention relates also to alkaline manganese dioxide-zinc primary or rechargeable cells, wherein the cathode structure is employed.

AB A pos. electrode for nonaq. electrolyte battery, comprising particles of a pos. electrode active substance and, dispersed therebetween, at least one alkaline earth metal oxide selected from the group consisting of magnesium oxide, calcium oxide and barium oxide. The electrode fabrication process includes steps of dispersing MnO₂ particles in an aqueous solution of alkaline earth metal hydroxide, drying the dispersion, heating at 290-310° to convert the hydroxide to oxide, pulverizing the mixture and compacting the powder. Primary batteries having the said electrodes are also disclosed. The nonaq. electrolyte for the primary batteries preferably contains a phosphazene derivative This pos. electrode enables enhancing the discharge capacity or charge-discharge capacity of nonaq. electrolyte battery immediately after production thereof and after storage at high temperature

AB The title cathode consisting of cubic Li Mn oxide has (1) F concentration-gradient layer, in which the depth of 10% difference of F concentration between the surface and the inner is 0.5-80 nm, (2) atomic ratio of F/Mn 0.002-0.05, and (3) lattice constant ≤ 0.82405 nm. The Li Mn oxide may contain B, Mg, Al, P, Ca, Ti, V, Cr, Fe, Co, Ni, Cu, Zn, Ba, Ga, and/or Ta. The title process contains firing mixts. containing Li compds., Mn, compds., and LiF at 500-800°, and washing unreacted LiF out with water. A secondary Li battery using the cathodes is also claimed.

AB The cathode is essentially unconstrained, i.e., no cage is used in the battery to confine the cathode. During discharge of the battery, the cathode may be inclined to swell, and during the charge cycle it may be inclined to contract or decrease its dimensions. However, the cathode is dimensioned so as to substantially fill the entire space allotted for it within the battery, while allowing for a slight accommodation for vertical or longitudinal expansion or growth in bobbin cells.

The cathode may include **additives** such as C or **graphite** to increase its elec. conductivity, hydrophobic agents such as PTFE, polyethylene, or polypropylene to enhance its H permeability and recombination rates, and similar hydrophobic agents as well as hydrophilic **additives** to serve as lubricants and to decrease tool wear during the manufacturing processes. The discharge capacity of the cathode may be established at .apprx.60-120% of the theor. 1-electron discharge capacity of the MnO₂ cathode.

AB This paper was focused on the development of prototypes for flat plate RAM (rechargeable alkaline manganese dioxide) batteries. In contrast to cathodes used in cylindrical RAM batteries, the mech. stability is a significant issue for the preparation of flat-plate cathodes. Therefore, the choice of an appropriate binder, e.g. Oppanol, is very important. In this work, an improved preparation process of flat-plate RAM cathodes was developed by investigating the single steps of the preparation method. It was further demonstrated that the most critical factor of zinc electrode performance was the electrolyte content of the anode gel. The best overall battery performance was achieved at 40% zinc amount and a Zn/ZnO ratio of 5.0, in combination with an electrolyte content of 50.5%. In order to stabilize the γ -structure of manganese dioxide and to enhance rechargeability, the addition of barium compds. was also studied. Battery cycling has shown that flat-plate RAM batteries with BaSO₄-modified cathodes outperformed control batteries by

24%, mainly because of the minimized fade of discharge capacity. Moreover, the admixt. of barium manganate to the **cathode** yielded more than 15% capacity improvement after 25 cycles, compared to the **barium sulfate** additive.

AB The cathode active mass contains 0.005-5% Ba compound and balance $\text{Li}_x\text{A}_y\text{MnO}_2$, where A = H, Na, K, Mg, Ca, Sr, Ti, V, Cr, Fe, Ni, Co, and/or Al; $0 < x < 1.5$; $0 < y < 1$, and $2 < z < 3$. The active mass is prepared by adding H_2O_2 to a 0.01-0.8M aqueous MnSO_4 solution at 10-80° under stirring; adding aqueous NH_3 to the solution; diluting the supernatant with an equal volume of water; adding aqueous BaCl_2 to the solution to precipitate BaSO_4 containing MnOOH ; filtering and drying the precipitate; adding oxide, hydroxide, chloride, and/or acetate of A to the precipitate; adding LiOH to the precipitate mixture at a Li/Mn ratio = 30-60; reacting the mixture under hydrothermal conditions at 140-300° for 2-30 h, washing the reaction product to $\text{pH} \leq 10$, and drying.

AB The batteries use cathodes composed of heat treated Li compound and **additive** containing **MnO₂**, where the Li compound is selected from LiOH, Li₂CO₃, and LiNO₃ and is added at a Li/Mn mol ratio (1-30):(70-99); the **additive** is ≥1 of hydroxides, carbonates, and nitrates of element M selected Na, K, Rb, Cs, Fr, Be, Mg, Ca, Sr, Ba, Ra, Fe, Al, B, Si, P, Ga, Ge, As, Se, In, Sn, Sb, Te, Pb, Po, and At at a M/Li mol ratio (10-40):(60-90). The heat treatment is carried out at 270-380°. These batteries have high capacity.

AB In order to satisfy basic battery characteristics for elec. vehicles (EV) such as
 specific energy, specific power and cycle life that are required for driving on
 urban streets, we have selected valve-regulated lead acid battery as a
 conventional battery and nickel/metal-hydride battery as an advanced battery, and
 have been studying on these development in order to put into practical use by
 1998. Regarding to nickel/metal-hydride battery, excellent nickel pos. electrode
 with high temperature charge efficiency accomplished with **additive**, such as Ca
 compound, and exceedingly good hydrogen absorbing alloy neg. electrode with high
 capacity and long cycle life, achieved by adjustment of alloy composition, surface
 treatment, and control of binder and conductive **additive** have been developed to
 overcome difficulties in scale up of battery size. Module battery using these
 technologies possessed specific energy twice (70 Wh/kg) as lead acid battery, and
 has superior specific power (160 Wh/kg) and long cycle life.

AB Elec. resistant glass film coatings on the neck or funnel part of **cathode** ray tubes (CRT) which decrease arcing are described. The glass film, containing V2O5 50-75, P2O5 15-40, ZnO and/or PbO 5-20 weight% and 0-15 weight% **additives** of **BaO**, Sb2O3, Li2O, **Mn oxide**, SiO2, B2O3, and MoO3 has softening pt. $\leq 475^\circ$, elec. resistance 0.1-100 M Ω /square, and flow ratio 3 and is substantially water-soluble. Thus, a glass fiber film composition containing V2O5 73, ZnO 5, P2O5 19, SiO2 1, and B2O3 2 weight% has elec. resistance 10.0 M Ω /square and is vitreous.

AB Brownish discoloration of **cathode** ray tube screen plates which occurs during use may be avoided without using costly **additives**, such as CeO₂, by addition of 0.01-0.2 weight % of MnO in conjunction with up to 0.5 weight % TiO₂. The amount of TiO₂ is never >3 times the weight of MnO and is adjusted so that the 4050 Å: 5460 Å wavelength relationship lies between 1:1 and 4:1. The glass has the formulation: SiO₂ 66, Al₂O₃ 4, **BaO** 12, PbO 2.5, K₂O 6, Na₂O 7, Li₂O 0.5, Rb₂O 0.4, F 1, and Sb₂O₃ and As₂O₃ 0.6%. Tables compare the results obtained (a) with varying amts. of MnO, (b) with varying amts. of MnO + TiO₂, (c) varying amts. of CeO₂ against controls of unmodified silica glass.

IC H01J

CC 57 (Ceramics)

IT Cathode-ray tubes

(glass for, containing **manganese oxide** and titanium oxide)
